The former ice extent was reconstructed by evaluating the distribution and character of erratics, glacial diamicts, and small-scale glacial bedforms such as striae, grooves, and chattermarks. The marine highstand was determined from raised beaches, marine terraces, wave-cut platforms and muddy sediments with in situ shells of *Laternula elliptica*. The altitude of lake sills and marine terraces was measured from above the modern high tide mark using an automatic level

Glacier morphology, or the form a glacier takes, is influenced by temperature, precipitation, topography, and other factors. The goal of glacial morphology is to gain a better understanding of glaciated landscapes, and the way they are shaped. Types of glaciers can range from massive ice sheets, such as the Greenland ice sheet, to small cirque glaciers found perched on mountain tops. Glaciers can be grouped into two main categories: Ice flow is constrained by the underlying bedrock topography

Glacial geomorphology is concerned principally with the role of glacial ice in landform and landscape evolution while periglacial geomorphology is fundamentally concerned with the development of landscapes in cold, nonglacial environments. Unlike the obviously profound impact glacial ice has on landscape evolution, periglacial conditions are often viewed as acting to modify landscapes in cold climates and not to form distinctive landscapes in their own right.

They are erosional forces because their ice carves the ground beneath them and on the sides, which forms a U-shaped valley, as with a valley glacier. Glaciers are also depositional because their movement pushes rocks and other debris into new areas. The sediment created when glaciers grind down rocks is called glacial rock flour. As glaciers melt, they drop

The scientific study of glacial processes and landforms formed in front of, beneath and along the margins of valley glaciers, ice sheets and other ice masses on the Earth's surface, both on land and in ocean basins, constitutes glacial geomorphology. The processes include understanding how ice masses move, erode, transport and deposit sediment.

Geomorphologists can piece together the history of such places by studying the remaining landforms and the sediments – often the particles and the organic material, such as pollen, beetles, diatoms and microfossils preserved in lake sediments and peat, can provide evidence on past climate change and processes.

While the tunnel construction through a glacial over-deepened valley presented in Case History 1.1 at Löttschberg occurred over 100 years ago, it is a classic example of the ability of a glacier to over-deepen a valley to such depths not thought conceivable from the scientific knowledge at that time; it was a case of an 'unknown unknown'. Today's updated landsystems approach to the understanding of these

Glaciers are accumulations of snow transformed into solid ice. Important questions of glacial geology concern the climatic controls that influence the occurrence of glaciers, the processes by which snow is transformed into ice, and the mechanism of the flow of ice within glaciers.
