Natural selection is a driving force in evolution and can generate populations that are better adapted to survive and successfully reproduce in their environments. But natural selection cannot produce the perfect organism. Natural selection can only select on existing variation in the population; it does not create anything from scratch.

To understand evolution, genetic variation is studied in populations. A population is defined as a group of individuals of the same species that interbreed. Members of a population share a common group of genes, called a gene pool. A gene pool consists of all the genes, including all the different alleles, that are present in

Guppies have some major advantages when it comes to using them as a model organism for evolutionary biology. Because of their isolation, guppy populations have been used to study the processes of “evolution” in the wild. These guppies have been used as model organisms for evolution since at least the 1970s.

~~Natural Selection in Guppies | Answers in Genesis~~

In each population, the allele will decrease in frequency for about 50 generations, then increase to stabilize at 50%. Because no migration can occur (the tubes are capped) we can rule out genetic drift.
